Abstract

An infant with hypoplastic left heart syndrome presented for surgical repair at 9 months of age, the ductus having remained open in the presence of a restrictive atrial septal defect. In addition, an anomalous left coronary artery originating from the right pulmonary artery was found. After preliminary blade/balloon atrial septostomy, a successful modified Norwood procedure with concomitant reimplantation of the anomalous coronary artery was performed.

Introduction

Without treatment, hypoplastic left heart syndrome (HLHS) is usually rapidly fatal either as a result of ductal closure and systemic hypoperfusion or due to overwhelming heart failure. Rarely, however, survival may be prolonged if the ductus remains open and a restrictive atrial septal defect sufficiently limits pulmonary blood flow. In infants with anomalous origin of the left coronary artery from the pulmonary artery, the anomalous coronary artery usually originates from the main pulmonary artery. Origin from the right pulmonary artery has been reported in only 3 patients [1-3]. We report our experience with a rare case of combined HLHS and anomalous left coronary artery originating from the right pulmonary artery

presenting for surgical management at 9 months of age.

The patient, born with HLHS variant, had the diagnosis made prenatally. Although the parents initially chose "compassionate care," the child survived. However, growth and development were poor, there was marked tachypnea, and the family decided to pursue surgical therapy at 8 months of age. Repeat evaluation revealed hypoplastic left ventricle and mitral valve with a 6.5-mm ascending aorta but hypoplastic transverse arch, coarctation, large patent ductus arteriosus, bilateral superior venae cavae, and a perimembranous ventricular septal defect. Patency of the ductus had permitted survival, but the lungs were markedly congested. A restrictive atrial septal defect was present [4], left atrial pressure was 30 mm Hg, and pulmonary artery pressure was systemic. In addition, the left coronary artery originated anomalously from the proximal right pulmonary artery (Fig 1). Pulmonary vascular resistance was high at 15 Wood U/m². To assess potential lability of pulmonary resistance, we performed limited blade/balloon atrial septostomy. Pulmonary blood flow increased (pulmonary-to-systemic flow ratio rose from 1:1 to 2.5:1) and pulmonary vascular resistance decreased to 8 Wood U/m². This suggested that pulmonary resistance could drop further after complete left atrial decompression, increasing the chance of operability. Therefore, we decided to proceed with a modified Norwood procedure [5] and concomitant reimplantation of the anomalous coronary artery.

Under hypothermic cardiopulmonary bypass, the distal branch pulmonary arteries were snared to preserve perfusion to the anomalous coronary. Under cardioplegic arrest, the ductus was ligated, the main pulmonary artery was transected just proximal to the bifurcation, and the anomalous coronary artery was excised from the right pulmonary artery with a generous cuff and translocated to the back wall of the proximal aorta. The cross-clamp was removed, all coronary arteries filled well, the heart started beating slowly while cooling continued, and the distal main and proximal right pulmonary arteries were repaired with autologous pericardium. At a nasopharyngeal temperature of 18°C, circulatory arrest was instituted and a modified Norwood procedure was performed as previously described [5].

Postoperative recovery was uneventful. Four months later, room air arterial saturation was 75% and follow-up catheterization demonstrated good ventricular function with no outflow obstruction and normal filling of the reimplanted coronary artery. On the basis of persistently moderately elevated pulmonary vascular resistance (3.3 Wood U/m²) responsive to oxygen, the patient was maintained on home oxygen to be reevaluated for possible bidirectional Glenn shunt in a few months.

Comment

[▲ Top](#)

Anomalous origin of the left coronary artery from the right pulmonary artery is a very rare anomaly [1–3], the repair of which by direct aortic implantation has only recently been reported [1]. Furthermore, we found only one autopsy report of combined HLHS with an anomalous coronary artery [6]. Survival beyond a few weeks of life in patients with HLHS receiving compassionate care alone is also quite rare, and in our case this became possible by a persistently patent ductus preserving systemic perfusion, in combination with a restrictive atrial septal defect limiting pulmonary blood flow. The resultant pulmonary hypertension could have precluded surgical palliation due to development of pulmonary vascular obstructive disease [4], but it did preserve perfusion of the anomalous coronary artery and ventricular function. Limited blade/balloon atrial septostomy demonstrated lability of the pulmonary vascular resistance and suggested operability. Combined repair involving coronary translocation as well as modified Norwood procedure [5] was successful, although future conversion to cavopulmonary shunt (and, ultimately, a Fontan circulation) still remains uncertain.
